Re: Shamrock Seed Project – Lighting Technical Memorandum

David J. Powers & Associates, Inc., on behalf of Santa Clara County, contracted Michael Baker International (Michael Baker) to prepare an environmental impact lighting study of the Shamrock Seed Project as required by the County of Santa Clara and the California Environmental Quality Act (CEQA). Michael Baker evaluated the environmental impact of the illumination from the proposed lighting to be installed as part of the project. We used AGi32 lighting analysis software to evaluate the effects of glare and trespass lighting across property lines. For this project, we developed a custom software solution based on the model presented by Garstang (1986) to calculate sky glow. We also visited the site on April 5, 2018, to measure the illumination levels from the existing greenhouses.

ENVIRONMENTAL IMPACTS

The proposed project being evaluated includes construction of two new greenhouse structures (measuring approximately 100 feet by 130 feet and 85 feet by 300 feet). These two greenhouses would be up to 22 feet tall, and composed of a translucent material to allow sunlight to enter during daylight hours. The greenhouses would be internally illuminated at night to provide a total of 16 hours of both natural and artificial lighting for the plants inside. The 16 hours of lighting would be continuous by supplementing natural day light with the artificial lighting in the morning or evening hours; hence, the duration of artificial lighting would vary depending upon the time of year.

The relevant significance criteria from Appendix G of the CEQA Guidelines for evaluating the potential lighting impacts of this project are as follows:

> *Would the project create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?*

This report evaluates three aspects of this impact:

- **Light Trespass.** Light trespass occurs when spill light is cast past the property line.
- **Glare.** Glare is described as difficulty seeing in the presence of bright light. It is a visual sensation caused by excessive and uncontrolled brightness.
- **Light Pollution (Uplight and Sky Glow).** The International Dark Sky Association describes this type as “brightening of the night sky caused by streetlights and other man-

1 Kaiser Plaza, Suite 1150, Oakland, CA 94612
P: (510) 879-0950 F: (510) 879-0960

> made sources, which has a disruptive effect on natural cycles and inhibits the observation of stars and planets."

The amount of uplight and glare from each fixture can be limited by locating the lamp/light source deep enough inside the body of the fixture that the lamp cannot be seen unless a person is standing directly underneath it. Light trespass is limited by using low lumen output fixtures that are low to the ground or fixtures which control the amount of light that extends beyond the property line. Sky glow is proportional to the total intensity of the lighting on the site, the total reflectivity of the ground (or the area under the lights), and the amount of light directed above the horizon. Sky glow can be limited by lowering the intensity of lights, eliminating light that is directed above the horizon, and covering illuminated areas.

POLICIES

Santa Clara County does not currently have any specific policies, ordinances, or codes with regard to lighting that would apply to this situation; however other counties in California do have some applicable codes that can be looked to as examples. The strictest example is Humboldt County Ordinance No. 2559, "Ordinance Making Clarifying and Corrective Amendments to Title III of the Humboldt County Code Relating to the Commercial Cultivation, Processing, Manufacturing and Distribution of Cannabis for Medical Use." While this ordinance is specific to cannabis cultivation, it includes language that could be applied to greenhouses in general, specifically 55.4.11(v), which states:

> Those cultivators using artificial lighting for mixed-light cultivation shall shield greenhouses so that little to no light escapes. Light shall not escape at a level that is visible from neighboring properties between sunset and sunrise.

The term "mixed-light" is defined as follows:

> "Mixed-Light" means cultivation using a combination of natural and supplemental artificial lighting at a maximum threshold as set forth in performance standards in Section 55.4.11(v), et seq. of this ordinance, or as to be determined by the Department of Food and Agriculture, whichever is less.

EXISTING LIGHTING

On April 5, 2018, Michael Baker documented and evaluated the existing lighting on the site using a light meter at least one hour after sunset. The existing on-site lighting emanated from two existing greenhouses illuminated with high pressure sodium and compact fluorescent lights.

Greenhouse 1 is about 3,000 square feet and currently has twelve 400-watt high pressure sodium lights mounted at approximately 9 feet above the ground, for a total of 4,800 watts and about 1.6 watts per square foot.

Greenhouse 2 is about 2,000 square feet and currently has approximately nine 32-watt compact fluorescent lights mounted at 9 feet above the ground, for a total of 288 watts and about 0.14 watts per square foot.

The total existing lighting is about 5,088 watts and 507,000 lumens.

The complete collection of existing lighting conditions can be found in *Appendix 1: Existing Light Measurements*. A photometric analysis can be found in *Appendix 2: Existing Site Photometrics*. We compare the existing and proposed lighting conditions below.

PROPOSED GREENHOUSES

The proposed greenhouses will be approximately 13,000 and 25,000 square feet, covering a total of approximately 38,000 square feet, or 7.6 times more area than the existing illuminated greenhouses.

The smaller proposed greenhouse will have 120 400-watt high pressure sodium lights mounted at approximately 9.5 feet, for a total of 48,000 watts and about 3.7 watts per square foot.

The larger proposed greenhouse will have 243 400-watt high pressure sodium lights mounted at approximately 9.5 feet, for a total of 97,200 watts and about 3.9 watts per square foot.

The proposed lighting is about 145,200 watts of high pressure sodium lighting, or about 28.5 times the existing lighting wattage, and about 14.5×10^6 lumens, or about 28.5 times the existing light output.

The complete photometric analysis of the proposed greenhouses can be found in *Appendix 3: Proposed Site Photometrics.*

TRESPASS

Light trespass occurs when spill light is cast past the property line. We used AGi32 to evaluate the amount of light from the existing greenhouses and from the proposed project that would fall on areas beyond the project's property line. Standards for light trespass vary, but typically should not be over 0.1 foot-candle (fc) 10 to 20 feet past the property line.[1] Light trespass is categorized as horizontal trespass and vertical illuminance.

The existing greenhouse lighting does not have any significant (>0.05 fc) horizontal trespass lighting. The full horizontal trespass can be found on page 7 of Appendix 2.

For the proposed project, as shown on pages 15-17 of Appendix 3, there would be some horizontal light trespass onto adjacent properties. The most significant area of trespass would be on the northwest side of the property near the larger of the two proposed greenhouses. The maximum light trespass value would be 0.3 fc right at the edge of the property, which quickly falls off to 0.1 fc within 10 feet of the property line. The full horizontal trespass calculation can be found on pages 15–17 of Appendix 3. Obtrusive light, or light that falls on a vertical plane at the property line, was measured by vertical illuminance at the northwest property line, where the proposed greenhouses would be closest to the property line. The applicable standard for obtrusive light is IDA/IES MLO-2011, which establishes a limit for a rural setting of about 0.1 fc at the property line.

The existing greenhouse lighting had a maximum vertical illuminance at the northwest property edge of 0.2 fc at the limit of the calculation grid 30 feet in the air. The average value was 0.02 fc

[1] A foot-candle is a unit of illumination equal to that given by a source of one candela at a distance of 1 foot (equivalent to one lumen per square foot or 10.764 lux).

over the entire northwest edge of the site. The full vertical illuminance calculation can be found on pages 3–6 of Appendix 2.

The vertical illuminance for the proposed project was measured using a grid that extended from the ground to 30 feet in the air (just over the height of the proposed greenhouses), with calculation points spaced 5 feet apart. The maximum calculated value of vertical illuminance would be 7.9 fc. The average for the entire northwest edge of the site would be 2.7 fc. The maximum value from the proposed project is 79 times higher than the limit set in IDA/IES MLO-2011, while the average is 27 times higher. The full vertical illuminance calculation can be found on pages 10–14 of Appendix 3.

GLARE

Glare is described as difficulty seeing in the presence of bright light. It is a visual sensation caused by excessive and uncontrolled brightness. Its effect can be disabling or simply uncomfortable. Glare is subjective, and sensitivity to glare can vary widely depending on the individual. Older people are usually more sensitive to glare due to the aging characteristics of the eye. Disability glare is the reduction in visibility caused by intense light sources in the field of view. This is the glare on a glossy magazine that makes it hard to read outside in bright sunlight.

The Glare Rating (GR) is a numerical evaluation of the amount of glare experienced by an observer. Veiling Luminance is the light reflected off a surface that obscures an object, making it difficult to see. It is used by AGi to calculate the Glare Rating, as shown below. GR runs from 10, which is unnoticeable, to 90, which is unbearable, actually causing pain. The level of GR that is acceptable depends on the application and task being performed. If a person is doing fine work, repairing a watch for example, the maximum desired GR is 45. If a ditch is being dug, a GR of 55 is acceptable. For the purposes of this report, the effect on the low light nature of the area is the primary concern, and the maximum acceptable GR is 20, which amounts to “barely noticeable.”[2] Each GR value is tied to one observer position.

The observer positions for this study are shown in the attached lighting summary and are labeled sequentially as Obs #1, Obs #2, etc. For example, a grid labeled Obs #1 has one observer position and would have a Glare Rating grid associated with it. AGi32 was used to evaluate the glare at seven points around the perimeter of the property as shown on page 2 of Appendix 3, with the locations chosen to reflect typical viewpoints of the property.

Evaluation Point	Glare Rating		
	Avg.	Max.	Min.
Glare Evaluation Point # 1	10.00	10	10
Glare Evaluation Point # 2	10.00	10	10
Glare Evaluation Point # 3	10.00	10	10
Glare Evaluation Point # 4	10.00	10	10
Glare Evaluation Point # 5	10.00	10	10

[2] Lighting Analysts, Inc., “Calculations Glare Rating Concepts” https://docs.agi32.com/AGi32/Content/adding_calculation_points/Calculations_Glare_Rating_Concepts.htm, 2018.

Glare Evaluation Point # 6	10.03	12	10
Glare Evaluation Point # 7	10.41	16	10

As summarized in the table and shown on pages 3–9 of Appendix 3, the glare from the proposed project would be barely discernable at its worst case and unnoticeable on average.

A glare evaluation was not done for the existing lighting as its results would be insignificant.

LIGHT POLLUTION (SKY GLOW)

Light pollution is defined by the International Dark Sky Association, and their definition is accepted by the Illuminating Engineering Society of North America, as "brightening of the night sky caused by streetlights and other man-made sources, which has a disruptive effect on natural cycles and inhibits the observation of stars and planets."

All of the fixtures evaluated for this report had no uplight, as they are full cutoff fixtures. Full cutoff is defined as a fixture having zero light emitted at or above horizontal. For a typical lighting application, this would be sufficient to ensure dark sky compliance. However, in this case, the downward-facing light is much more intense than typical and so requires a more detailed look.

Initial lighting calculations for light reflected upward were done in AGi32, using equivalent lights for the greenhouse lighting because the photometric files for specified lights were not available. The lights selected as equivalents are Lithonia KAD 400S, which are also 400W high pressure sodium lights with a wide distribution. Because AGi32 doesn't have the ability to calculate sky glow, a calculation grid was placed at cloud level (6,000 feet), facing down, and used to calculate what the illuminance on the clouds would be. The maximum illuminance value at cloud level was approximately 0.03 fc. For reference, the illuminance on the ground during a full moon is approximately 0.01 fc, or one-third the illumination that the greenhouses are putting on clouds at a height of 6,000 feet. The illumination at this altitude is >0.01 fc to a radius of approximately 1 mile from the center of the site. This analysis shows that the amount of reflected light from the greenhouses is substantial, but does not provide enough data to conclude whether the new lighting would negatively affect sky brightness.

A grid was also placed at the same height above the simulation of the existing lighting, but no measurable (>0.001 fc) cloud level illumination was present.

Following this initial analysis, a more detailed analysis was done using the model described by Garstang.[3] His model was used to create a computer program that can calculate how a light source affects the brightness of the sky, and the values for the greenhouses were used to calculate a set of values for the sky for an observer on the edge of the property, as well as 5 km away. All calculations were done for zenith distances of 0–80 degrees, and for 30 degrees to the side of the center of the site. The calculations to the side of the site are symmetrical, so only one side was calculated. The results have the brightness listed in nanolamberts (nL), and the factor of the natural sky brightness (factor) has been included for the maximum and minimum values as shown below. These and other units used for measuring the brightness of the sky are shown in Figure 1. The natural sky has a brightness of approximately 59.2 nL.

[3] Garstang, R. H., "Model for Artificial Night-Sky Illumination," 1986.

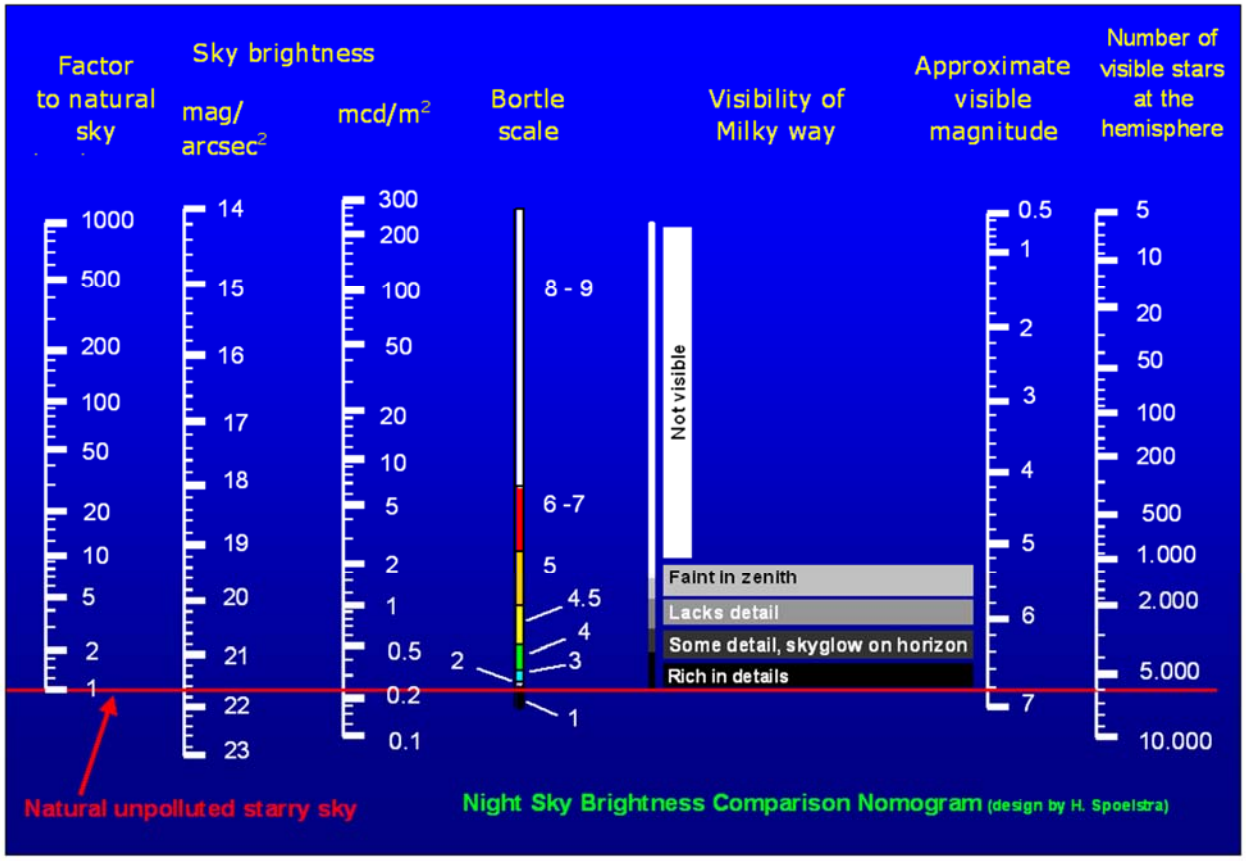

Figure 1: Night Sky Brightness Comparison Nomogram from www.darkskiesawareness.org

To calculate the sky glow caused by the greenhouse, a total lumen output of about 14.5 mega lumens (Ml) was calculated (40,000 lumens per fixture, 363 fixtures). This value was reduced to 80%, or 11.6 Ml, to account for losses through the glass. An additional light loss factor for the age and condition of the bulbs was not used since the environmental impact should account for the worst case. A ground reflectivity of 0.15 was used, which is the typical value used by Garstang. The site diameter was set to 400 meters, and an aerosol density of around 4/cm^3 (which is about an Air Quality Index of 150) was used as a worst-case scenario.

The International Astronomical Union (IAU) has suggested that man-made light not increase the brightness of the night sky by more than 10% (or a factor of 0.1) at a zenith distance of 45 degrees for a location to be considered a dark site.[4] This area is not a dark site, and so a higher value might be considered. However, it is also only one property, so a value of over 10% would seem to be an excessive allowance. Based on these arguments, it was decided that a value of 10% would be used as an acceptable cutoff. The detailed results are found in *Appendix 4: Compiled Sky Brightness*, which also contains a complete list of the settings used for each of the calculations.

[4] Smith, F. G., “Report and Recommendations of IAU Commission 50,” 1979.

Sky Brightness Due to Proposed Greenhouses

	Maximum @ 45° zenith distance (nL)	Maximum @ 45° zenith distance (factor)	Maximum @ zenith (nL)	Maximum @ zenith (factor)
Edge of Property	1.52	0.026	0.473	0.008
5 km from Property	0.058	0.001	0.013	2.2×10^{-4}

As can be seen, our simulation shows that the sky brightness due to the proposed greenhouses would be well below the 10% (0.1 factor) recommendation both at the property edge and at a distance of 5 km. The complete sky brightness results can be found on pages 6–7 of Appendix 4.

Sky Brightness Due to Existing Greenhouses

	Maximum @ 45° zenith distance (nL)	Maximum @ 45° zenith distance (factor)	Maximum @ zenith (nL)	Maximum @ zenith (factor)
Edge of Property	0.152	0.0026	0.016	2.7×10^{-4}
5 km from Property	0.041	6.9×10^{-4}	4.7×10^{-4}	7.9×10^{-6}

The proposed lighting would increase the current sky glow caused by the greenhouses and seen from the edge of the property by about 10 times at a 45 degree zenith distance and by about 30 times at zenith. From a distance of 5 km, the increase is only 1.4 times at a 45 degree zenith distance and about 28 times at zenith. The complete sky brightness results can be found on pages 4–5 of Appendix 4.

We also ran simulations to determine the approximate sky brightness in the site vicinity due to nearby cities to evaluate the effect of the additional light from the proposed greenhouses. Detailed results can be found on pages 1–3 of Appendix 4.

Sky Brightness Due to Adjacent Cities

	Maximum @ 45° zenith distance (nL)	Maximum @ 45° distance source (factor)	Maximum at zenith (nL)	Maximum at zenith (factor)
San Jose	50.6	0.85	13.55	0.23
Salinas	4.47	0.075	1.08	0.018
Gilroy	23.8	0.40	6.20	0.10

The sky glow of nearby cities is significantly brighter than the sky glow that will be caused by the new greenhouses. If the observer was near the greenhouse and facing San Jose, the sky glow from San Jose at a 45 degree zenith distance would be 33 times brighter than that from the proposed greenhouses, while the brightness at zenith from these three cities combined would be 44 times brighter than the sky glow at zenith from the proposed greenhouses.

Existing vs Proposed Sky Brightness

The total existing sky brightness can be calculated by adding the sky brightness caused by each source at zenith together. Below is a comparison of the current sky brightness with the brightness change caused by the proposed greenhouses.

	Existing @ zenith (factor)	Proposed @ zenith (factor)	% Change
Edge of Property	0.348	0.356	2.2%
5 km from Property	0.348	0.348	0%

The difference threshold for light, or how much of a difference in brightness is noticeable by humans, is about 8%. The increase in night sky brightness caused by the proposed greenhouses is only about 2% at zenith, and would not be noticeable.

CONCLUSION

The proposed greenhouses will cause minimal glare, trespass, and sky glow, all close to or well within any established standard. However, they will have a significant impact on vertical illuminance that requires mitigation. The projected vertical illuminance at the northwest property line would be very high; at approximately 79 times the maximum allowed by IDA/IES MLO-2011.

Our recommendation is that the County require the applicant to install a solid barrier on the northwest side of the proposed greenhouses to reduce the vertical illuminance at the northwest property line to levels below those specified in IDA/IES MLO-2011. The barrier is required to have an opacity of at least 80% and be at least as tall as the greenhouses. The most appropriate solution is a shade or other similar barrier that is attached or placed adjacent to the greenhouses.
